

Day-9 Sorting Algorithm

Quick Sort:-

51	95	66	72	42	38	39	41	15
<u>0</u>	1	2	3	4	5	6	7	8

Step-1) Decide left & right
left = 0, right = 8

Step-2) Select pivot element which is the first element of array
pivot = arr[left] = 51

Step-3) Find out the exact posⁿ of pivot by using no. of less than that pivot
count \Rightarrow no. of ele that is less than pivot
count = 5
swap (arr[count], arr[left])
pivot

```
int partition (int left, int right)
{
    int pivot = arr[left];
    int count = 0;
    for (int i = left + 1; i <= right; i++)
    {
        if (arr[i] < pivot)
        {
            count++;
        }
    }
    int p = left + count;
    swap (arr[left], arr[p]);
    int i = left, j = right;
```

Step-5) Two pointers i & j

Compare \checkmark $\text{arr}[i] < \text{pivot}$ & $\text{arr}[j] > \text{pivot}$ \times
 $\text{swap}(\text{arr}[i], \text{arr}[j])$

```

while ( i < p & j > p )
{
    while ( arr[i] < pivot )
    {
        i++;
    }
    while ( arr[j] > pivot )
    {
        j--;
    }
    swap ( arr[i], arr[j] )
}
return p;

```

```

void QuickSort ( int left, int right )
{
    if ( left < right )
    {
        int p = partition ( left, right );
        QuickSort ( left, p-1 );
        QuickSort ( p+1, right );
    }
}

```

Quick Sort = $O(n \log n)$

$$\text{work} = O(n^2)$$

* Search Algorithm:-

1) Linear Search:- arr

key = 72

0	1	2	3	4	5
98	47	53	12	7	33

Time Complexity = $O(\underline{\underline{n}})$

2) Binary Search :-

Divide & Conquer

	0	1	2	3	4	5	6
arr	98	47	53	12	7	33	51

Key = 12

key = S3

low = 0, mid = 3, high = 6

7	12	33	47	51	53	98
---	----	----	----	----	----	----

↑ mid

step-1) Find out mid index & their value

$$\text{mid} = \text{low} + (\text{high} - \text{low}) / 2;$$

$$\text{arr}[\text{mid}] = \text{arr}[\underline{3}] = \underline{47}$$

step-2) Compare Search
ele with mid
value

✓ if ($\text{arr}[\text{mid}] == \text{key}$)
return mid;

step-3) Compare search ele > arr[mid]
12 > 47

search (mid+1, right)

step-4) Compare search ele < arr[mid]

search (left, mid-1)

void Bsearch (int low, int high, int arr[]) $\leftarrow \text{key} < \text{mid}$

{

while (low <= high)

{
int mid = $\text{low} + (\text{high} - \text{low}) / 2;$ ↓

if ($\text{arr}[\text{mid}] == \text{key}$)

return mid;

```

    if ( arr[mid] > key)
        high = mid - 1;
    if (arr[mid] < key)
        low = mid + 1;
    }
    return -1;
}

```
