

Day No. 23

Tree

- Tree :- $\Rightarrow$ It is a nonlinear data structures
- $\Rightarrow$ On top we have root node & root nodes they have child nodes
- $\Rightarrow$ Nodes are connected in Hierarchical fashion (we store the data in Hierarchy fashion)
- $\Rightarrow$ One node may be connected to multiple child nodes.

Linear DS

1) Array :-

0	1	2	3	4	5
21	54				
1000	1004				

2) Stack
Queue

-	top	-	rear
-		-	
-	LIFO	-	FIFO

3) Linked List

Visualization of Tree (Representation)

* Terminology in Tree

Application of Tree

1) Hierarchy Data to store

2) Social Media applⁿ

3) Inside the graph for traversing

4) Expression solve

* Types of Tree :-

1) General Tree :-

→ No limitation for the child nodes

2) Binary Tree

⇒ Each node have at most 2 child
(0, 1, 2)

⇒ But the elements are not stored in seqⁿ

26, 12, 14, 17, 16, 15

3) Full Binary Tree / Strict Binary Tree :-

⇒ every node has either 0 or 2 child

4) Complete Binary Tree:-

⇒ Every node have either 0 or 1 or 2 child

⇒ But we have to insert in the fashion of left to right and complete the level.

26, 12, 14, 72, 96, 97, 87, 15, 24

⑤ Skew Binary Tree:-

Left
Skew Tree

Right Skew Tree

Examples :-

FBT ✓
CBT ✗

FBT ✗

* Binary Tree Representation :-

A) Array Representation

B) Linked List Representation

⇒ Drawback ⇒ memory wastage
⇒ Always we used this representation

A) Array Representation :-

Values	1	2	3	4	5	6	7
Index	0	1	2	3	4	5	6

We insert the de in
array like wise from
left to right level wise

Find out child nodes from parent node index as well as find out parent node index from child node index from Array.

Values	1	2	3	4	6	5	7
index	0	1	2	3	4	5	6

2 $\Rightarrow$ parent $\Rightarrow$ index $\Rightarrow$ child ?
index

$$\left\{ \begin{array}{l} \text{left child index} = (\text{parent index} * 2) + 1 \\ \text{right child index} = (\text{parent index} * 2) + 2 \end{array} \right.$$

e.g. $\left. \begin{array}{l} \text{left index} = (1 * 2) + 1 = 3 \Rightarrow 4 \\ \text{right index} = (1 * 2) + 2 = 4 \Rightarrow 6 \end{array} \right\}$

$$\left\{ \begin{array}{l} \text{parent index} = \left\lfloor \frac{\text{left index}}{2} \right\rfloor \rightarrow \text{Floor} \\ \text{parent index} = \left\lfloor \frac{\text{right index}}{2} - 1 \right\rfloor \end{array} \right.$$

e.g. $\frac{3}{2} = \lfloor 1.5 \rfloor = 1$
 $\frac{4}{2} - 1 = 2 - 1 = 1$

Disadvantage of Array Representation:-

Node = 6

Array of size = 15

10	5	15	null	null	20	30	null	null	null	null	25	null	null	null
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14

15
- 6

9 — location $\Rightarrow$ null
Wastage of memory

B) Linked List Representation :- chain of nodes

memory $\Rightarrow$

```

class TNode
{
    int data;
    TNode left;
    TNode right;

    public TNode(int data)
    {
        this.data = data;
        left = null;
        right = null;
    }
}
  
```

after the constructor

execution of code left data right

Diagram showing the creation of a TNode object:

```

graph TD
    Code[TNode obj = new TNode(10);] --> Node3[TNode]
    subgraph Node3 [TNode]
        direction LR
        left3((left)) --- data3 --- right3((right))
        data3 --- null3[null]
        data3 --- 10[10]
        data3 --- null4[null]
    end
    left3 --> obj_ptr[obj]
    right3 --> right_ptr[right]
  
```

The code TNode obj = new TNode(10); creates a new TNode object. The object has left = null, data = 10, and right = null. The variable obj points to the left field, and the variable right points to the right field.
